1 Vector Space

1.1 Vector Space $(V, +, \times)$ (over a field \mathbb{F})

A vector space over a field \mathbb{F} is a set V w/ an operation addition $+: V \times V \rightarrow V$ and an operation scalar multiplication $\mathbb{F} \times V \rightarrow V$

- (1) Addition is associative & commutative
- (2) $\exists 0 \in V$, additive identity: $0 + v = v \forall v \in V$
- (3) $1v = v \forall v \in V$ (where $1 \in \mathbb{F}$ is multi. id. in \mathbb{F})
- (4) $\forall \alpha, \beta \in \mathbb{F}, v \in V, \alpha(\beta v) = (\alpha\beta)v$
- (5) $\forall v \in V, (-1)v = -v$ we have $v + (-v) = 0$
- (6) $\forall \alpha \in \mathbb{F}, v, u \in V, \alpha(v + u) = \alpha v + \alpha u$
- (7) $\forall \alpha, \beta \in \mathbb{F}, v \in V, (\alpha + \beta)v = \alpha v + \beta v$

1.2 A field is a vector space over its subfield

Example 1. $\mathbb{K} \subset \mathbb{F}$ is a subfield of a field \mathbb{F} . Then \mathbb{F} is a vector space over \mathbb{K} . (Since $\mathbb{F} \subset \mathbb{F}[x]$, then $\mathbb{F}[x]$ is a vector space over \mathbb{F} .)

1.3 Vector subspace

Suppose that V is a vector space over \mathbb{F} . A vector subspace or just subspace is a nonempty subset $W \subset V$ closed under addition and scalar multiplication. i.e. $v + w \in W, av \in W, \forall v, w \in W, a \in \mathbb{F}$.

Example 2. $\mathbb{K} \subset \mathbb{L} \subset \mathbb{F}$, then \mathbb{L} is a subspace of \mathbb{F} over \mathbb{K} .

1.4 Linear independent, Linear combination

1.5 span V , basis, dimension

A set of elements $v_1, \dots, v_n \in V$ is said to **span** V if every vector $v \in V$ can be expressed as a linear combination of v_1, \dots, v_n . If v_1, \dots, v_n spans and is linearly independent, then we call the set a **basis** for V .

Proposition 1 (Proposition 2.4.10.). Suppose V is a vector space over a field \mathbb{F} having a basis $\{v_1, \dots, v_n\}$ with $n \geq 1$.

- (i) For all $v \in V$, $v = a_1v_1 + \dots + a_nv_n$ for exactly one $(a_1, \dots, a_n) \in \mathbb{F}^n$.
- (ii) If w_1, \dots, w_n span V , then they are linearly independent.
- (iii) If w_1, \dots, w_n are linearly independent, then they span V .

If a vector space V over \mathbb{F} has a basis with n vectors, then V is said to be n -dimensional (over \mathbb{F}) or is said to have **dimension** n .

1.6 Standard basis vectors

$$e_1 = (1, 0, \dots, 0), e_2 = (0, 1, 0, \dots, 0), \dots, e_n = (0, 0, \dots, 0, 1) \in \mathbb{F}^n$$

are a basis for \mathbb{F}^n called the **standard basis vectors**.

1.7 Linear transformation

Given two vector spaces V and W over \mathbb{F} a **linear transformation** is a function $T : V \rightarrow W$ such that for all $a \in \mathbb{F}$ and $v, w \in V$, we have

$$T(av) = aT(v) \text{ and } T(v + w) = T(v) + T(w)$$

Proposition 2 (Proposition 2.4.15.). *If V and W are vector spaces and v_1, \dots, v_n is a basis for V then any function from $\{v_1, \dots, v_n\} \rightarrow W$ extends uniquely to a linear transformation $V \rightarrow W$.*

Any $v \in V$, $\exists (a_1, \dots, a_n)$ s.t. $v = a_1v_1 + \dots + a_nv_n$. Then $T(v) = T(a_1v_1 + \dots + a_nv_n) = a_1T(v_1) + \dots + a_nT(v_n)$

1.8 一个线性变换对应一个矩阵, 线性变换矩阵相乘仍为线性变换矩阵

Corollary 1 (Corollary 2.4.16.). *If v_1, \dots, v_n is a basis for a vector space V and w_1, \dots, w_m is a basis for a vector space W (both over \mathbb{F}), then any linear transformation $T : V \rightarrow W$ determines (and is determined by) the $m \times n$ matrix:*

$$A = A(T) = \begin{bmatrix} A_{11} & A_{12} & \dots & A_{1n} \\ A_{21} & A_{22} & \dots & A_{2n} \\ \vdots & \vdots & \dots & \vdots \\ A_{m1} & A_{m2} & \dots & A_{mn} \end{bmatrix}$$

$$\begin{bmatrix} w_1 & \dots & w_m \end{bmatrix}^T = A \begin{bmatrix} v_1 & \dots & v_n \end{bmatrix}^T$$

$\mathcal{L}(V, W)$ denotes the set of all linear transformations from V to W ; $M_{m \times n}(\mathbb{F})$ the set of $m \times n$ matrix with entries in \mathbb{F} . $T \rightarrow A(T)$ defines a *bijection* $\mathcal{L}(V, W) \rightarrow M_{m \times n}(\mathbb{F})$. $A(T)$ **represents the linear transformation T** .

Proposition 3 (Proposition 2.4.19). *Suppose that V , W , and U are vector spaces over \mathbb{F} , with fixed chosen bases. If $T : V \rightarrow W$ and $S : W \rightarrow U$ are linear transformations represented by matrices $A = A(T)$ and $B = B(S)$, then $ST = S \circ T : V \rightarrow U$ is a linear transformation represented by the matrix $BA = B(S)A(T)$.*

1.9 GL(V): invertible linear transformations $V \rightarrow V$

Given a vector space V over F , we let $GL(V) \subset \mathcal{L}(V, V)$ denote the subset of **invertible linear transformations**.

$$GL(V) = \{T \in \mathcal{L}(V, V) | T \text{ is a bijection}\} = \mathcal{L}(V, V) \cap Sym(V)$$

2 Eigenvalues Related

2.1 Eigenvalues, Eigenvectors

2.1.1 Definition

A vector x is an **eigenvector** of a matrix A if Ax is parallel to x , that is if $Ax = \lambda x$ for some number $\lambda \in \mathbb{R}$. The number λ is called an **eigenvalue** of A .

i.e. the root of $(A - \lambda I_n)x = 0 \Leftrightarrow \det(A - \lambda I_n) = 0$

2.1.2 Diagonalizable Matrix

A $n \times n$ matrix A with n linearly independent eigenvalues u is said to be *diagonalizable*.

$$\begin{aligned} AU &= A \begin{bmatrix} | & | & \cdots & | \\ u_1 & u_2 & \cdots & u_n \\ | & | & \cdots & | \end{bmatrix} \\ &= \begin{bmatrix} | & | & \cdots & | \\ \lambda_1 u_1 & \lambda_2 u_2 & \cdots & \lambda_n u_n \\ | & | & \cdots & | \end{bmatrix} \\ &= \begin{bmatrix} | & | & \cdots & | \\ u_1 & u_2 & \cdots & u_n \\ | & | & \cdots & | \end{bmatrix} \begin{bmatrix} \lambda_1 & & & \\ & \lambda_2 & & \\ & & \ddots & \\ & & & \lambda_n \end{bmatrix} \\ &= UD \\ \Rightarrow A &= UDU^{-1} \end{aligned}$$

Theorem 1. If an $n \times n$ matrix A has n linearly independent eigenvectors u_1, \dots, u_n corresponding to eigenvalues $\lambda_1, \dots, \lambda_n$, then $A = UDU^{-1}$ where D is diagonal with entries $\lambda_1, \dots, \lambda_n$, and U has columns u_1, \dots, u_n .

A is **similar** to D ($\exists P$ s.t. $A = PDP^{-1}$).

Not *diagonalizable* is also called *defective*.

Theorem 2. An $n \times n$ matrix with n distinct eigenvalues is diagonalizable.

(Because the n associated eigenvectors are always linearly independent.)

2.2 Jacobian matrix

Suppose $\mathbf{f} : \mathbf{R}^n \rightarrow \mathbf{R}^m$ is a function such that each of its first-order partial derivatives exist on \mathbf{R}^n . This function takes a point $\mathbf{x} \in \mathbf{R}^n$ as input and produces the vector $\mathbf{f}(\mathbf{x}) \in \mathbf{R}^m$ as output. Then the Jacobian matrix of \mathbf{f} is defined to be an $m \times n$ matrix, denoted by \mathbf{J} , whose (i, j) th entry is $\mathbf{J}_{ij} = \frac{\partial f_i}{\partial x_j}$, or explicitly

$$\mathbf{J} = \begin{bmatrix} \frac{\partial \mathbf{f}}{\partial x_1} & \cdots & \frac{\partial \mathbf{f}}{\partial x_n} \end{bmatrix} = \begin{bmatrix} \nabla^T f_1 \\ \vdots \\ \nabla^T f_m \end{bmatrix} = \begin{bmatrix} \frac{\partial f_1}{\partial x_1} & \cdots & \frac{\partial f_1}{\partial x_n} \\ \vdots & \ddots & \vdots \\ \frac{\partial f_m}{\partial x_1} & \cdots & \frac{\partial f_m}{\partial x_n} \end{bmatrix}$$

where $\nabla^T f_i$ is the transpose (row vector) of the gradient of the i component.

2.3 Hessian matrix

Suppose $f : \mathbb{R}^n \rightarrow \mathbb{R}$ is a function taking as input a vector $\mathbf{x} \in \mathbb{R}^n$ and outputting a scalar $f(\mathbf{x}) \in \mathbb{R}$. If all second partial derivatives of f exist and are continuous over the domain of the function, then the Hessian matrix \mathbf{H} of f is a square $n \times n$ matrix, usually defined and arranged as follows:

$$\mathbf{H}_f = \begin{bmatrix} \frac{\partial^2 f}{\partial x_1^2} & \frac{\partial^2 f}{\partial x_1 \partial x_2} & \cdots & \frac{\partial^2 f}{\partial x_1 \partial x_n} \\ \frac{\partial^2 f}{\partial x_2 \partial x_1} & \frac{\partial^2 f}{\partial x_2^2} & \cdots & \frac{\partial^2 f}{\partial x_2 \partial x_n} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial^2 f}{\partial x_n \partial x_1} & \frac{\partial^2 f}{\partial x_n \partial x_2} & \cdots & \frac{\partial^2 f}{\partial x_n^2} \end{bmatrix},$$

or, by stating an equation for the coefficients using indices i and j ,

$$(\mathbf{H}_f)_{i,j} = \frac{\partial^2 f}{\partial x_i \partial x_j}.$$

The Hessian matrix is a symmetric matrix, since the hypothesis of continuity of the second derivatives implies that the order of differentiation does not matter (Schwarz's theorem).

The determinant of the Hessian matrix is called the Hessian determinant.

2.4 Positive Definite Matrices

2.4.1 Definition

We say that a symmetric $n \times n$ matrix A is:

- (1). **positive semidefinite** (written $A \succeq 0$) if $x^T A x \geq 0$ for all x .
- (2). **positive definite** (written $A \succ 0$) if $x^T A x > 0$ for all $x \neq 0$.
- (3). **negative semidefinite** (written $A \preceq 0$) if $x^T A x \leq 0$ for all x .
- (4). **negative definite** (written $A \prec 0$) if $x^T A x < 0$ for all $x \neq 0$.
- (5). **indefinite** (not written in any particular way) if none of the above apply.

$x^T A x$ is a function of x called the quadratic form associated to A .

Note: $A^T A$ is **positive semidefinite**, since $x^T A^T A x = \|Ax\|^2 \geq 0$.

2.4.2 Diagonal matrix situation

$$D = \begin{bmatrix} d_1 & 0 & \dots & 0 \\ 0 & d_2 & \dots & 0 \\ \dots & \dots & \dots & \dots \\ 0 & 0 & \dots & d_n \end{bmatrix}$$

Lemma 1. *If d_1, \dots, d_n are all nonnegative, then $D \succeq 0$;*

If d_1, \dots, d_n are all positive, then $D \succ 0$;

If d_1, \dots, d_n are all nonpositive, then $D \preceq 0$;

If d_1, \dots, d_n are all negative, then $D \prec 0$;

2.4.3 Using eigenvalues

If A is an $n \times n$ symmetric matrix, then it can be factored as

$$A = Q^T \Lambda Q = Q^T \begin{bmatrix} \lambda_1 & 0 & \dots & 0 \\ 0 & \lambda_2 & \dots & 0 \\ \dots & \dots & \dots & \dots \\ 0 & 0 & \dots & \lambda_n \end{bmatrix} Q$$

where $\lambda_1, \dots, \lambda_n$ are the eigenvalues of A and the columns of Q are the corresponding eigenvectors.

We can get $x^T A x = x^T Q^T \Lambda Q x = (Qx)^T \Lambda (Qx)$

If we substitute $y = Qx$:

$$x^T A x = y^T \Lambda y = \lambda_1 y_1^2 + \lambda_2 y_2^2 + \dots + \lambda_n y_n^2$$

Theorem 3.

If $\lambda_1, \dots, \lambda_n$ are all nonnegative, then symmetric matrix $A \succeq 0$;

If $\lambda_1, \dots, \lambda_n$ are all positive, then $A \succ 0$;

If $\lambda_1, \dots, \lambda_n$ are all nonpositive, then $A \preceq 0$;

If $\lambda_1, \dots, \lambda_n$ are all negative, then $A \prec 0$;

if it has both positive and negative eigenvalues, then A is indefinite

2.4.4 Sylvester's Criterion

Consider a $n \times n$ matrix A :

$$A = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \dots & \dots & \dots & \dots \\ a_{n1} & a_{n2} & \dots & a_{nn} \end{bmatrix}$$

Denote its $k \times k$ submatrix $A^{(k)}$:

$$A^{(k)} = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1k} \\ a_{21} & a_{22} & \dots & a_{2k} \\ \dots & \dots & \dots & \dots \\ a_{k1} & a_{k2} & \dots & a_{kk} \end{bmatrix}$$

Let $\Delta_k = \det(A^{(k)})$

$$\det(A - xI) = (\lambda_1 - x)(\lambda_2 - x)\dots(\lambda_n - x)$$

by setting $x = 0$ we get $\det(A) = \lambda_1\lambda_2\dots\lambda_n$. When $A \succ 0$, all the eigenvalues are positive, so $\det(A) > 0$ as well.

$A \succ 0 \Rightarrow \mathbf{u}^T A \mathbf{u} > 0$ for all \mathbf{u} :

Set $\mathbf{u} = [0, 0, \dots, 0, u_{k+1}, u_{k+2}, \dots, u_n]$

Then we can simplify the quadratic form for A to the quadratic form for $A^{(k)}$. Therefore, we expect $A^{(k)} \succ 0 \Rightarrow \Delta_k > 0$ for all k .

Theorem 4.

$A \succ 0$ iff $\Delta_i > 0 \forall i = 1, \dots, n$

$A \prec 0$ iff $(-1)^i \Delta_i > 0 \forall i = 1, \dots, n$

A is indefinite if the first Δ_k (nonzero) that breaks each pattern respectively is the wrong sign.

3 Euclidean geometry basics

3.1 Norm

3.1.1 Vector's Norm

Vector $x \in \mathbb{R}^n$ -n-dim Euclidean space

$$x = (x_1, \dots, x_n) \equiv \begin{bmatrix} x_1 & x_2 & \dots & x_n \end{bmatrix}^\top = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix}$$

Norm of x , $\|x\|$ satisfies properties:

- (a) $\|x\| \geq 0$
- (b) $\|x\| = 0 \Leftrightarrow x = 0$
- (c) $\|cx\| = |c|\|x\|$, for $c \in \mathbb{R}$
- (d) $\|x + y\| \leq \|x\| + \|y\| \leftarrow$ Triangle Ineq.

Euclidean Norm (default $\rho = 2$): $\|x\| = \sqrt{x^\top x} = \sqrt{\sum_{i=1}^n x_i^2}$

Other norms:

1. l_1 -norm : $\|x\|_1 = \sum_{i=1}^n |x_i|$
2. l_ρ -norm : $\|x\|_\rho = \sqrt[\rho]{\sum_{i=1}^n |x_i|^\rho}$
3. Supremum norm or l_∞ -norm : $\|x\|_\infty = \max_i |x_i|$

3.1.2 Matrix's Norm

$A \in \mathbb{R}^{n \times m}$ is a matrix

$$\|Ax\| \leq \|A\|\|x\|, \|AB\| \leq \|A\|\|B\|$$

Default is $\rho = 1$: $\|A\| = \max_{\|x\|=1} \|Ax\|$. 即找到最大的绝对值和的“列”。

$$\|A\|_F = \sqrt{\sum_{i,j} a_{ij}^2} \quad (\text{Frobenius norm})$$

$$\|A\|_1 = \max_j \sum_{i=1}^n |A_{ij}| \quad [\text{II}]$$

$$\|A\|_\infty = \max_i \sum_{j=1}^n |A_{ij}| \quad [\square]$$

$$\|A\|_2 = \max_k \sigma_k, \sigma_k \text{ is the singular value of } A$$

$$\|A\| = \max \left(\frac{\|A \times\|}{\| \times\|} \right) \Rightarrow \|A\| \geq \frac{\|A \times\|}{\| \times\|}$$

$$\|A \times\| \leq \|A\|\| \times\|$$

3.2 Euclidean distance, inner product

Euclidean distance on \mathbb{R}^n :

$$\|x - y\| = \sqrt{(x_1 - y_1)^2 + \dots + (x_n - y_n)^2}$$

Euclidean inner product:

$$x \cdot y = x_1 y_1 + \dots + x_n y_n = x^T y$$

Two important results for Euclidean norm:

- 1) Pythagorean Theorem: If $x^\top y = 0$,

$$\|x + y\|^2 = \|x\|^2 + \|y\|^2$$

- 2) Cauchy - Schwarz Inequality:

$$|x^\top y| \leq \|x\| \|y\|$$

$$" = " \text{ iff } x = \alpha y \text{ for some } \alpha \in \mathbb{R}$$

3.3 Isometry

An **isometry** of \mathbb{R}^n is a bijection $\Phi : \mathbb{R}^n \rightarrow \mathbb{R}^n$ that preserves distance, which means,

$$|\Phi(x) - \Phi(y)| = |x - y|, \quad \forall x, y \in \mathbb{R}^n$$

We use $Isom(\mathbb{R}^n)$ denotes the set of all isometries of \mathbb{R}^n ,

$$Isom(\mathbb{R}^n) = \{\Phi : \mathbb{R}^n \rightarrow \mathbb{R}^n | |\Phi(x) - \Phi(y)| = |x - y|, \quad \forall x, y \in \mathbb{R}^n\}$$

Proposition 4. $\Phi, \Psi \in Isom(\mathbb{R}^n)$, then $\Phi \circ \Psi, \Phi^{-1} \in Isom(\mathbb{R}^n)$

证明.

Since Φ, Ψ are bijections, so is $\Phi \circ \Psi$. Moreover,

$$|\Phi \circ \Psi(x) - \Phi \circ \Psi(y)| = |\Phi(\Psi(x)) - \Phi(\Psi(y))| = |\Psi(x) - \Psi(y)| = |x - y|$$

Since $id \in Isom(\mathbb{R}^n)$,

$$|x - y| = |id(x) - id(y)| = |\Phi \circ \Phi^{-1}(x) - \Phi \circ \Phi^{-1}(y)| = |\Phi^{-1}(x) - \Phi^{-1}(y)|$$

□

3.4 Linear isometries i.e. orthogonal group

There is a matrix $A \in GL(n, \mathbb{R})$ i.e. a *invertible linear transformations* $T_A : \mathbb{R}^n \rightarrow \mathbb{R}^n$ is given by $T_A(v) = Av$.

$$T_A(v) \cdot T_A(w) = (Av) \cdot (Aw) = (Av)^t(Aw) = v^t A^t Aw$$

$$A^t A = I \Leftrightarrow T_A(v) \cdot T_A(w) = v \cdot w \Leftrightarrow T_A \in Isom(\mathbb{R}^n)$$

We define the all isometries in *invertible linear transformations* $\mathbb{R}^n \rightarrow \mathbb{R}^n$ as **orthogonal group**

$$O(n) = \{A \in GL(n, \mathbb{R}) | A^t A = I\} \subset GL(n, \mathbb{R})$$

3.5 Special orthogonal group

$O(n)$ are the matrices representing linear isometries of \mathbb{R}^n . $1 = \det(I) = \det(A^t A) = \det(A^t) \det(A) = \det(A)^2 \Rightarrow \det(A) = 1$ or $\det(A) = -1$. We use **special orthogonal group** represents A with $\det(A) = 1$,

$$SO(n) = \{A \in O(n) | \det(A) = 1\}$$

3.6 translation

Define a *translation* by $v \in \mathbb{R}^n$,

$$\tau_v : \mathbb{R}^n \rightarrow \mathbb{R}^n, \tau_v(x) = x + v$$

Note 1 (Exercise 2.5.3). $\forall v \in \mathbb{R}^n, \tau_v$ is an isometry.

证明. $|\tau_v(x) - \tau_v(y)| = |(x + v) - (y + v)| = |x - y|$

□

3.7 All isometries can be represented by a composition of *a translation* and *an orthogonal transformation*

Since *the composition of isometries is an isometry*, $\forall A \in O(n)$ and $v \in \mathbb{R}^n$, the composition

$$\Phi_{A,v}(x) = \tau_v(T_A(x)) = Ax + v$$

is an isometry. **which could account for all isometries.**

Theorem 5. $Isom(\mathbb{R}^n) = \{\Phi_{A,v} | A \in O(n), v \in \mathbb{R}^n\}$

4 Algebra Computation

4.1 Random Vectors

Mean:

$$\mu = \mathbb{E}(\mathbf{Z}) = \begin{pmatrix} \mathbb{E}(Z_1) \\ \mathbb{E}(Z_2) \\ \dots \\ \mathbb{E}(Z_m) \end{pmatrix}$$

Variance-Covariance matrix Σ :

$$\Sigma_{m \times m} = Cov(\mathbf{Z}) = \mathbb{E}((\mathbf{Z} - \mu)(\mathbf{Z} - \mu)^T) = \begin{bmatrix} Var(Z_1) & \dots & Cov(Z_1, Z_m) \\ \dots & \dots & \dots \\ Cov(Z_m, Z_1) & \dots & Var(Z_m) \end{bmatrix}$$

Affine Transformation

(1)

$$\mathbf{W} = \mathbf{a}_{n \times 1} + \mathbf{B}_{n \times m} \mathbf{Z}_{m \times 1}$$

$$\mathbb{E}(\mathbf{W}) = \mathbf{a} + \mathbf{B}\mu, \quad Cov(\mathbf{W}) = \mathbf{B}\Sigma\mathbf{B}^T$$

(2)

$$\mathbf{W} = \mathbf{v}^T \mathbf{Z} = v_1 Z_1 + \dots + v_m Z_m$$

$$\mathbb{E}(\mathbf{W}) = \mathbf{v}^T \mu = \sum_{i=1}^m v_i \mu_i$$

$$Var(\mathbf{W}) = \mathbf{v}^T \Sigma \mathbf{v} = \sum_{i=1}^m v_i^2 Var(Z_i) + 2 \sum_{i < j} v_i v_j Cov(Z_i, Z_j)$$

$$\text{i.e. } \mathbb{E}(\mathbf{AZ}) = \mathbf{A}\mathbb{E}(Z); \quad Var(\mathbf{AZ}) = \mathbf{A}Var(\mathbf{Z})\mathbf{A}^T$$

(3)

$$Cov(\mathbf{AX}, \mathbf{BY}) = \mathbb{E}[(\mathbf{AX} - \mathbf{A}\mathbb{E}(X))(\mathbf{BY} - \mathbf{B}\mathbb{E}(Y))^T] = \mathbf{A}\mathbb{E}[(\mathbf{X} - \mathbb{E}(X))(\mathbf{Y} - \mathbb{E}(Y))^T]\mathbf{B}^T = \mathbf{A}Cov(\mathbf{X}, \mathbf{Y})\mathbf{B}^T$$

$u = u(x)$	$\frac{\partial g(u)}{\partial x} =$	$\frac{\partial g(u)}{\partial u} \frac{\partial u}{\partial x}$	$\frac{\partial u}{\partial x} \frac{\partial g(u)}{\partial u}$
$u = u(x)$	$\frac{\partial f(g(u))}{\partial x} =$	$\frac{\partial f(g)}{\partial g} \frac{\partial g(u)}{\partial u} \frac{\partial u}{\partial x}$	$\frac{\partial u}{\partial x} \frac{\partial g(u)}{\partial u} \frac{\partial f(g)}{\partial g}$

图 1: Denominator layout means $x \in \mathbb{R}^{n \times 1}$

$$\begin{aligned}\frac{\partial u}{\partial x^T} &= \left(\frac{\partial u^T}{\partial x}\right)^T \\ \frac{\partial u^T v}{\partial x} &= \frac{\partial u^T}{\partial x} v + \frac{\partial v^T}{\partial x} u^T \\ \frac{\partial uv^T}{\partial x} &= \frac{\partial u}{\partial x} v^T + u \frac{\partial v^T}{\partial x} \\ \frac{\partial x^T x}{\partial x} &= 2x \\ \frac{\partial x^T Ax}{\partial x} &= (A + A^T)x\end{aligned}$$

where $x, u, v \in \mathbb{R}^{n \times 1}$

Note:

$$\frac{d\|Aw - b\|^2}{dw} = \frac{d(Aw - b)^T(Aw - b)}{dw} = \frac{d(Aw - b)^T}{dw}(Aw - b) + \frac{d(Aw - b)^T}{dw}(Aw - b) = 2A(Aw - b)$$

Matrix by vector:

$$\frac{\partial AB}{\partial x} = \frac{\partial A}{\partial x} B + A \frac{\partial B}{\partial x}$$

Matrix by matrix:

$$\begin{aligned}\frac{\partial u^T X v}{\partial X} &= uv^T \\ \frac{\partial u^T X^T X u}{\partial X} &= 2Xuu^T \\ \frac{\partial [(Xu - v)^T(Xu - v)]}{\partial X} &= 2(Xu - v)u^T\end{aligned}$$

Trace (迹):

$$\begin{aligned}
 \text{tr}(a) &= a \\
 \text{tr}(AB) &= \text{tr}(BA) \\
 \text{tr}(ABC) &= \text{tr}(CAB) = \text{tr}(BCA) \\
 \frac{\partial \text{tr}(AB)}{\partial A} &= B^T \\
 \text{tr}(A) &= \text{tr}(A^T) \\
 \frac{\partial \text{tr}(ABA^T C)}{\partial A} &= CAB + C^T AB^T
 \end{aligned}$$

4.3 LU Decomposition

Triangular matrix saves time when computing $Ax = b$.

Let A be a square matrix. An LU factorization refers to the factorization of A , with proper row and/or column orderings or permutations, into two factors – a lower triangular matrix L and an upper triangular matrix U :

$A = LU$. In the lower triangular matrix all elements above the diagonal are zero, in the upper triangular matrix, all the elements below the diagonal are zero. For example, for a 3×3 matrix A , its LU decomposition looks like this:

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} = \begin{bmatrix} \ell_{11} & 0 & 0 \\ \ell_{21} & \ell_{22} & 0 \\ \ell_{31} & \ell_{32} & \ell_{33} \end{bmatrix} \begin{bmatrix} u_{11} & u_{12} & u_{13} \\ 0 & u_{22} & u_{23} \\ 0 & 0 & u_{33} \end{bmatrix}.$$

$$A = PLU$$

P is a permutation matrix (used to swap row, only one 1 in every row). P is orthogonal, so $P^{-1} = P^T$.

Solve $Ax = b$:

$$Ax = b$$

$$PLUx = b$$

Let $y = Ux$, then solve $PLy = b$

$$Ly = P^T b$$

Complexity: $O(n^3)$
